Introduction to Software Testing
Chapter 3.2 Logic Coverage

Paul Ammann & Jeff Offutt

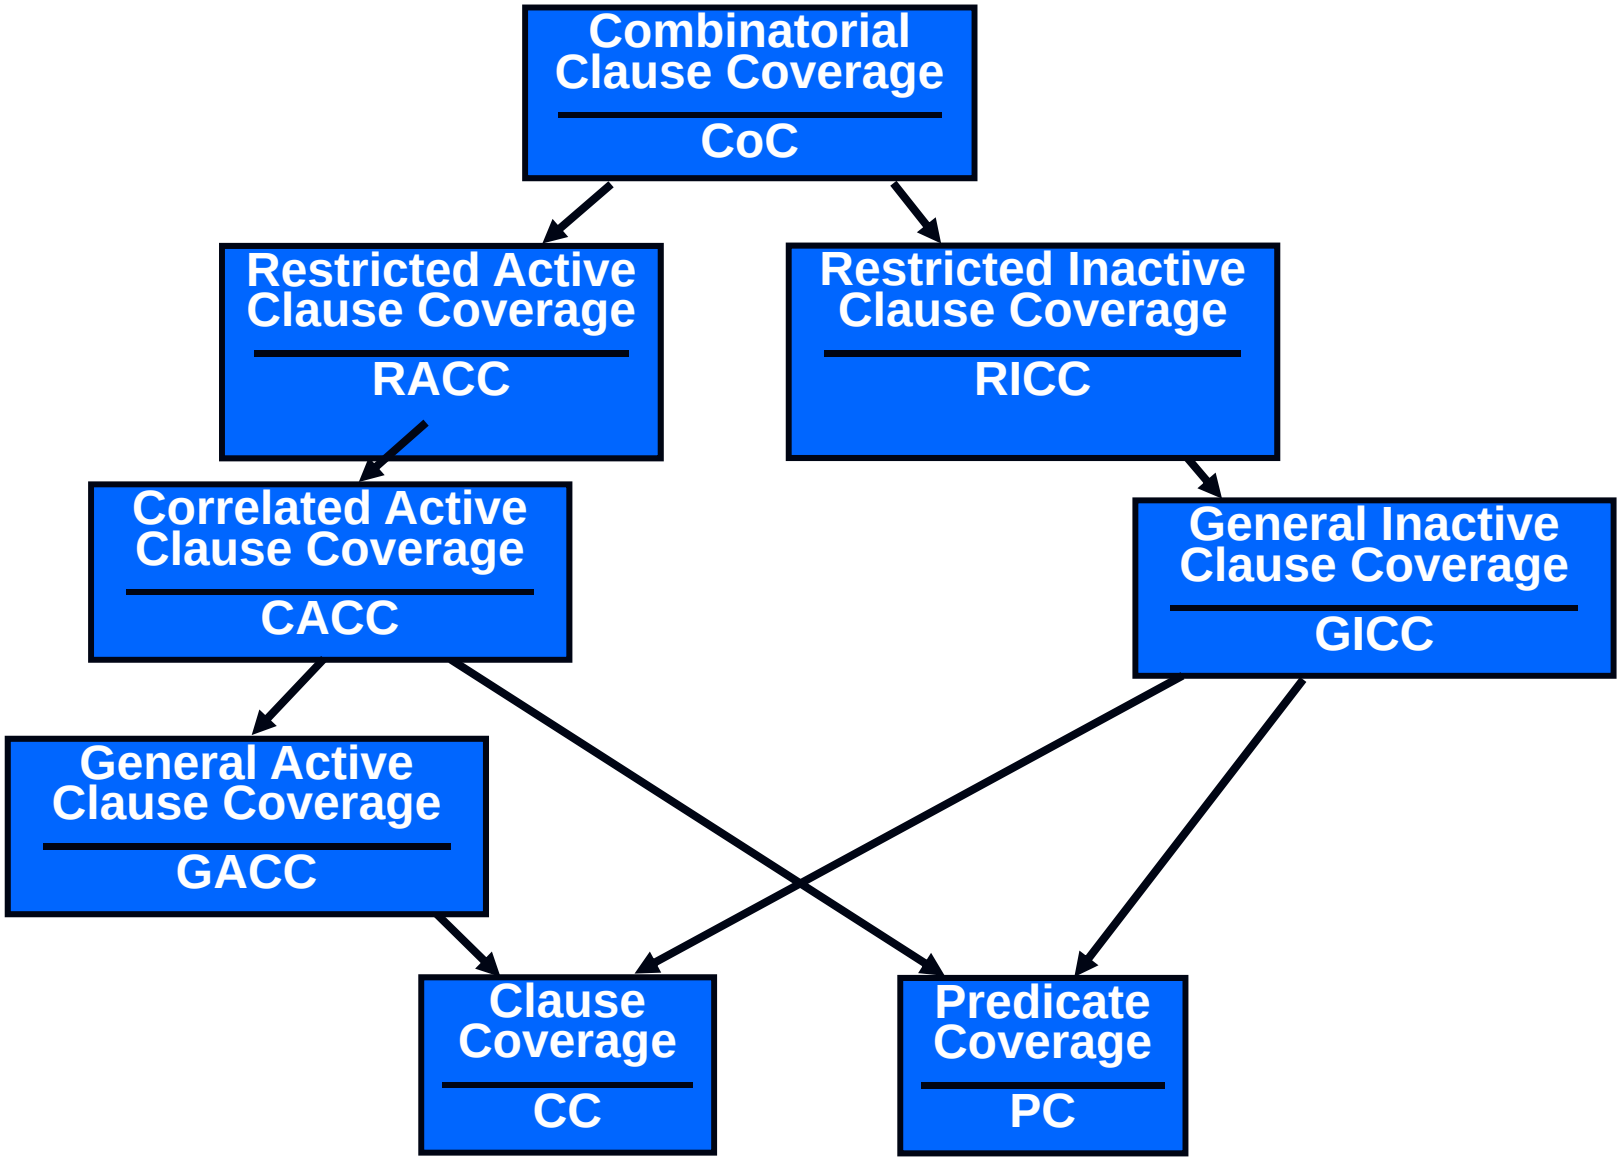
KAIST

Covering Logic Expressions

- Logic expressions show up in many situations
- Covering logic expressions is required by the US Federal Aviation Administration for safety critical software
- Logical expressions can come from many sources
  - Decisions in programs
  - FSMs and statecharts
  - Requirements
- Tests are intended to choose some subset of the total number of truth assignments to the expressions

KAIST

Logic Coverage Criteria Subsumption



KAIST

Logic Predicates and Clauses

- A *predicate* is an expression that evaluates to a boolean value
- Predicates can contain
  - boolean variables
  - non-boolean variables that contain >, <, ==, >=, <=, !=
  - boolean function calls
- Internal structure is created by logical operators
  - $\neg$ – the *negation* operator
  - $\wedge$ – the *and* operator
  - $\vee$ – the *or* operator
  - $\rightarrow$ – the *implication* operator
  - $\oplus$ – the *exclusive or* operator
  - $\leftrightarrow$ – the *equivalence* operator
- A *clause* is a predicate with no logical operators

KAIST

Examples

- (a < b) ∨ f (z) ∧ D ∧ (m >= n*o)
- Four clauses:
  - (a < b) – relational expression
  - f (z) – boolean-valued function
  - D – boolean variable
  - (m >= n*o) – relational expression
- Most predicates have few clauses
- Sources of predicates
  - Decisions in programs
  - Guards in finite state machines
  - Decisions in UML activity graphs
  - Requirements, both formal and informal
  - SQL queries

Testing and Covering Predicates

- We use predicates in testing as follows :
  - Developing a model of the software as one or more predicates
  - Requiring tests to satisfy some combination of clauses

- Abbreviations:
  - P is the set of predicates
  - p is a single predicate in P
  - C is the set of clauses in P
  - C_p is the set of clauses in predicate p
  - c is a single clause in C

KAIST

Predicate and Clause Coverage

- The first (and simplest) two criteria require that each predicate and each clause be evaluated to both true and false

Predicate Coverage (PC) : **For each *p* in *P*, *TR* contains two requirements: *p* evaluates to true, and *p* evaluates to false.**

a.k.a. "decision coverage" in literature

- **When predicates come from conditions on edges, this is equivalent to edge coverage**
- **PC does not evaluate all the clauses, so …**

Clause Coverage (CC) : **For each *c* in *C*, *TR* contains two requirements: *c* evaluates to true, and *c* evaluates to false.**

KAIST **a.k.a. "condition coverage" in literature**

Predicate Coverage Example

((a < b) ∨ D) ∧ (m >= n*o)

predicate coverage

Predicate = true

a = 5, b = 10, D = true, m = 1, n = 1, o = 1
= (5 < 10) ∨ true ∧ (1 >= 1*1)
= true ∨ true ∧ TRUE
= true

Predicate = false

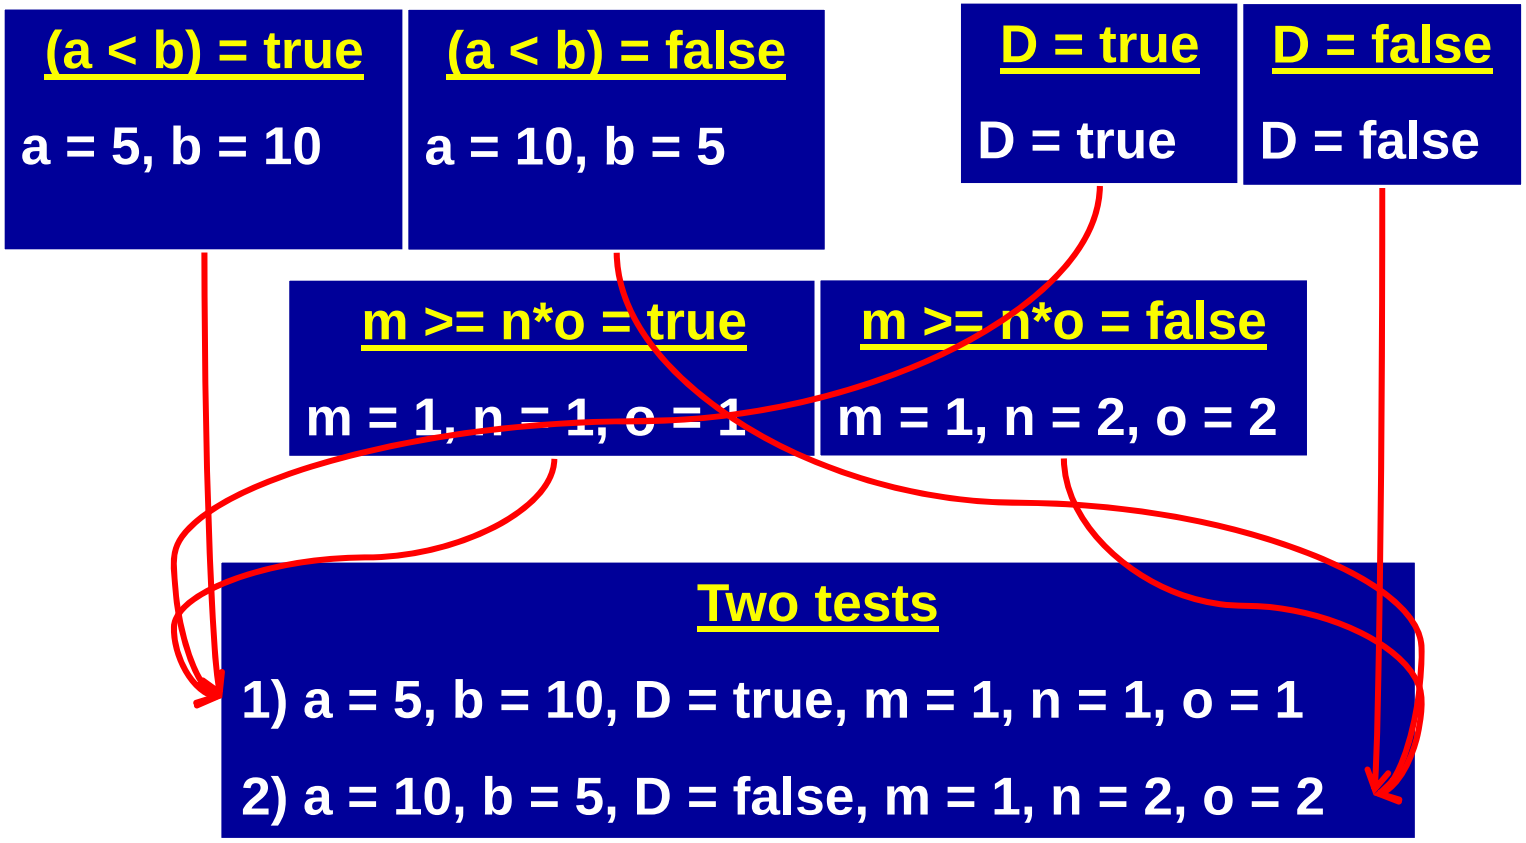
a = 10, b = 5, D = false, m = 1, n = 1, o = 1
= (10 < 5) ∨ false ∧ (1 >= 1*1)
= false ∨ false ∧ TRUE
= false

KAIST

Clause Coverage Example

((a < b) ∨ D) ∧ (m >= n*o)

Clause coverage



KAIST

Problems with PC and CC

- PC does not fully exercise all the clauses, especially in the presence of short circuit evaluation
- CC does not always ensure PC
  - That is, we can satisfy CC without causing the predicate to be both true and false
    - Ex. $x > 3 \rightarrow x > 1$
      - Two test cases { x=4, x=0} satisfy CC but not PC
  - This is definitely not what we want !
- Condition/decision coverage is a hybrid metric composed by the union of CC and PC
  - Modified condition/decision coverage (MC/DC) checks every condition can affect decision
  - equivalent to condition/decision coverage for C/Java (w/ short circuit)
- The simplest solution is to test all combinations …

Combinatorial Coverage

- CoC requires every possible combination
- Sometimes called Multiple Condition Coverage

Combinatorial Coverage (CoC) : For each p in P, TR has test requirements for the clauses in C_p to evaluate to each possible combination of truth values.

	a < b	D	m >= n*o	((a < b) ∨ D) ∧ (m >= n*o)
1	T	T	T	T
2	T	T	F	F
3	T	F	T	T
4	T	F	F	F
5	F	T	T	T
6	F	T	F	F
7	F	F	T	F
8	F	F	F	F

KAIST

Combinatorial Coverage

- This is simple, neat, clean, and comprehensive …
- **But quite expensive!**
- **2^N tests, where *N* is the number of clauses**
  - **Impractical for predicates with more than 3 or 4 clauses**
- **The literature has lots of suggestions – some confusing**
- **The general idea is simple:**

Test each clause independently from the other clauses

- **Getting the details right is hard**
- **What exactly does "independently" mean ?**
- **The book presents this idea as "*making clauses active*"**

…

KAIST

Active Clauses

- Clause coverage has a weakness
  - The values do not always make a difference to a whole predicate
- To really test the results of a clause, the clause should be the determining factor in the value of the predicate

Determination :

A clause C_i in predicate p, called the major clause, determines p if and only if the values of the remaining minor clauses C_j are such that changing C_i changes the value of p

- **This is considered to make the clause c_i active**

KAIST

Determining Predicates

P = A ∨ B

if *B* = *true*, *p* is always true.

so if *B* = *false*, *A* determines *p*.

if *A* = *false*, *B* determines *p*.

P = A ∧ B

if *B* = *false*, *p* is always false.

so if *B* = *true*, *A* determines *p*.

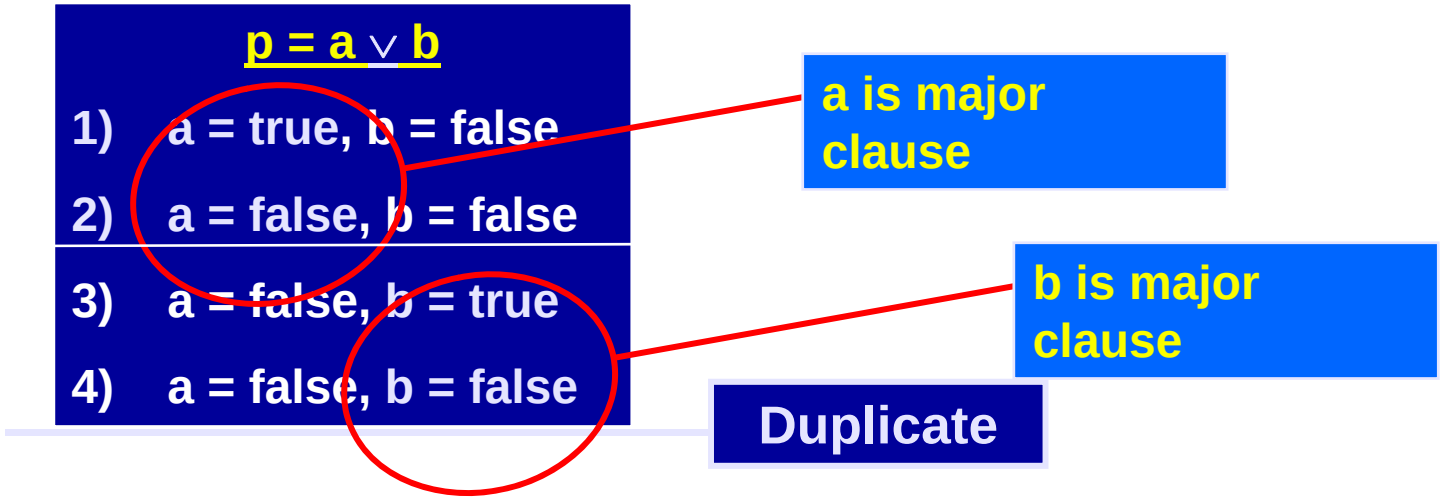
if *A* = *true*, *B* determines *p*.

- Goal : Find tests for each clause when the clause determines the value of the predicate
- This is formalized in several criteria that have subtle, but very important, differences

KAIST

Active Clause Coverage

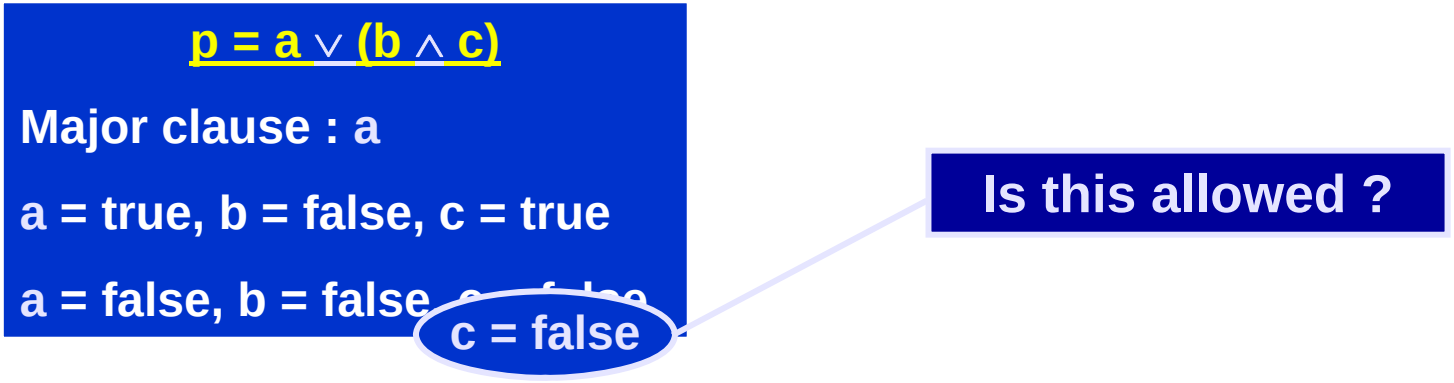
Active Clause Coverage (ACC) : For each p in P and each major clause c_i in C_p, choose minor clauses c_j, j != i, so that c_i determines p. TR has two requirements for each c_i : c_i evaluates to true and c_i evaluates to false.



- This is a form of MCDC, which is required by the Federal Avionics Admini stration (FAA) for safety critical software
- Ambiguity : Do the minor clauses have to have the same values when the major clause is true and false?

KAIST

Resolving the Ambiguity



- This question caused confusion among testers for years
- Considering this carefully leads to three separate criteria :
  - Minor clauses do not need to be the same (GACC)
  - Minor clauses do need to be the same (RACC)
  - Minor clauses force the predicate to become both true and false (CACC)

KAIST

General Active Clause Coverage

General Active Clause Coverage (GACC) : For each *p* in *P* and each major clause c_i in *Cp*, choose minor clauses c_j, *j != i*, so that c_i determines *p*. TR has two requirements for each c_i : c_i evaluates to true and c_i evaluates to false.

The values chosen for the minor clauses c_j do not need to be the same when c_i is true as when c_i is false, that is, $c_j(c_i = true) = c_j(c_i = false)$ for all c_j OR $c_j(c_i = true) != c_j(c_i = false)$ for all c_j.

- It is possible to satisfy GACC without satisfying predicate coverage
  - Ex. p = a ↔ b,
    - {TT, FF} satisfies GACC, but not PC
- We want to cause predicates to be both true and false !

KAIST

Restricted Active Clause Coverage

Restricted Active Clause Coverage (RACC) : For each *p* in *P* and each major clause c_i in *Cp*, choose minor clauses c_j, *j != i*, so that c_i determines *p*. TR has two requirements for each c_i: c_i evaluates to true and c_i evaluates to false.

The values chosen for the minor clauses c_j must be the same when c_i is true as when c_i is false, that is, it is required that $c_j(c_i = true) = c_j(c_i = false)$ for all c_j.

- This has been a common interpretation by aviation developers
- RACC often leads to infeasible test requirements
- There is no logical reason for such a restriction

KAIST

Correlated Active Clause Coverage

Correlated Active Clause Coverage (CACC) : For each *p* in *P* and each major clause *ci* in *Cp*, choose minor clauses c_j, *j != i*, so that c_i determines *p*. TR has two requirements for each c_i: c_i evaluates to true and c_i evaluates to false.

The values chosen for the minor clauses c_j must cause *p* to be true for one value of the major clause c_i and false for the other, that is, it is required that *p(c_i = true) != p(c_i = false)*.

- A more recent interpretation
- Implicitly allows minor clauses to have different values
- Explicitly satisfies (subsumes) predicate coverage

KAIST

CACC and RACC

	a	b	c	a ∧ (b ∨ c)
1	T	T	T	T
2	T	T	F	T
3	T	F	T	T
5	F	T	T	F
6	F	T	F	F
7	F	F	T	F

major clause

CACC can be satisfied by choosing any of rows 1, 2, 3 AND any of rows 5, 6, 7 – a total of nine pairs

	a	b	c	a ∧ (b ∨ c)
1	T	T	T	T
5	F	T	T	F
2	T	T	F	T
6	F	T	F	F
3	T	F	T	T
7	F	F	T	F

major clause

RACC can only be satisfied by one of the three pairs above

Inactive Clause Coverage

- The active clause coverage criteria ensure that “major” clauses do affect the predicates
- Inactive clause coverage takes the opposite approach – major clauses do not affect the predicates

Inactive Clause Coverage (ICC) : For each *p* in *P* and each major clause c_i in *Cp*, choose minor clauses c_j, *j != i*, so that c_i does not determine *p*. TR has four requirements for each c_i:

(1) **c_i evaluates to true with *p* true**

(2) **c_i evaluates to false with *p* true**

(3) **c_i evaluates to true with *p* false, and**

(4) **c_i evaluates to false with *p* false.**

KAIST

General and Restricted ICC

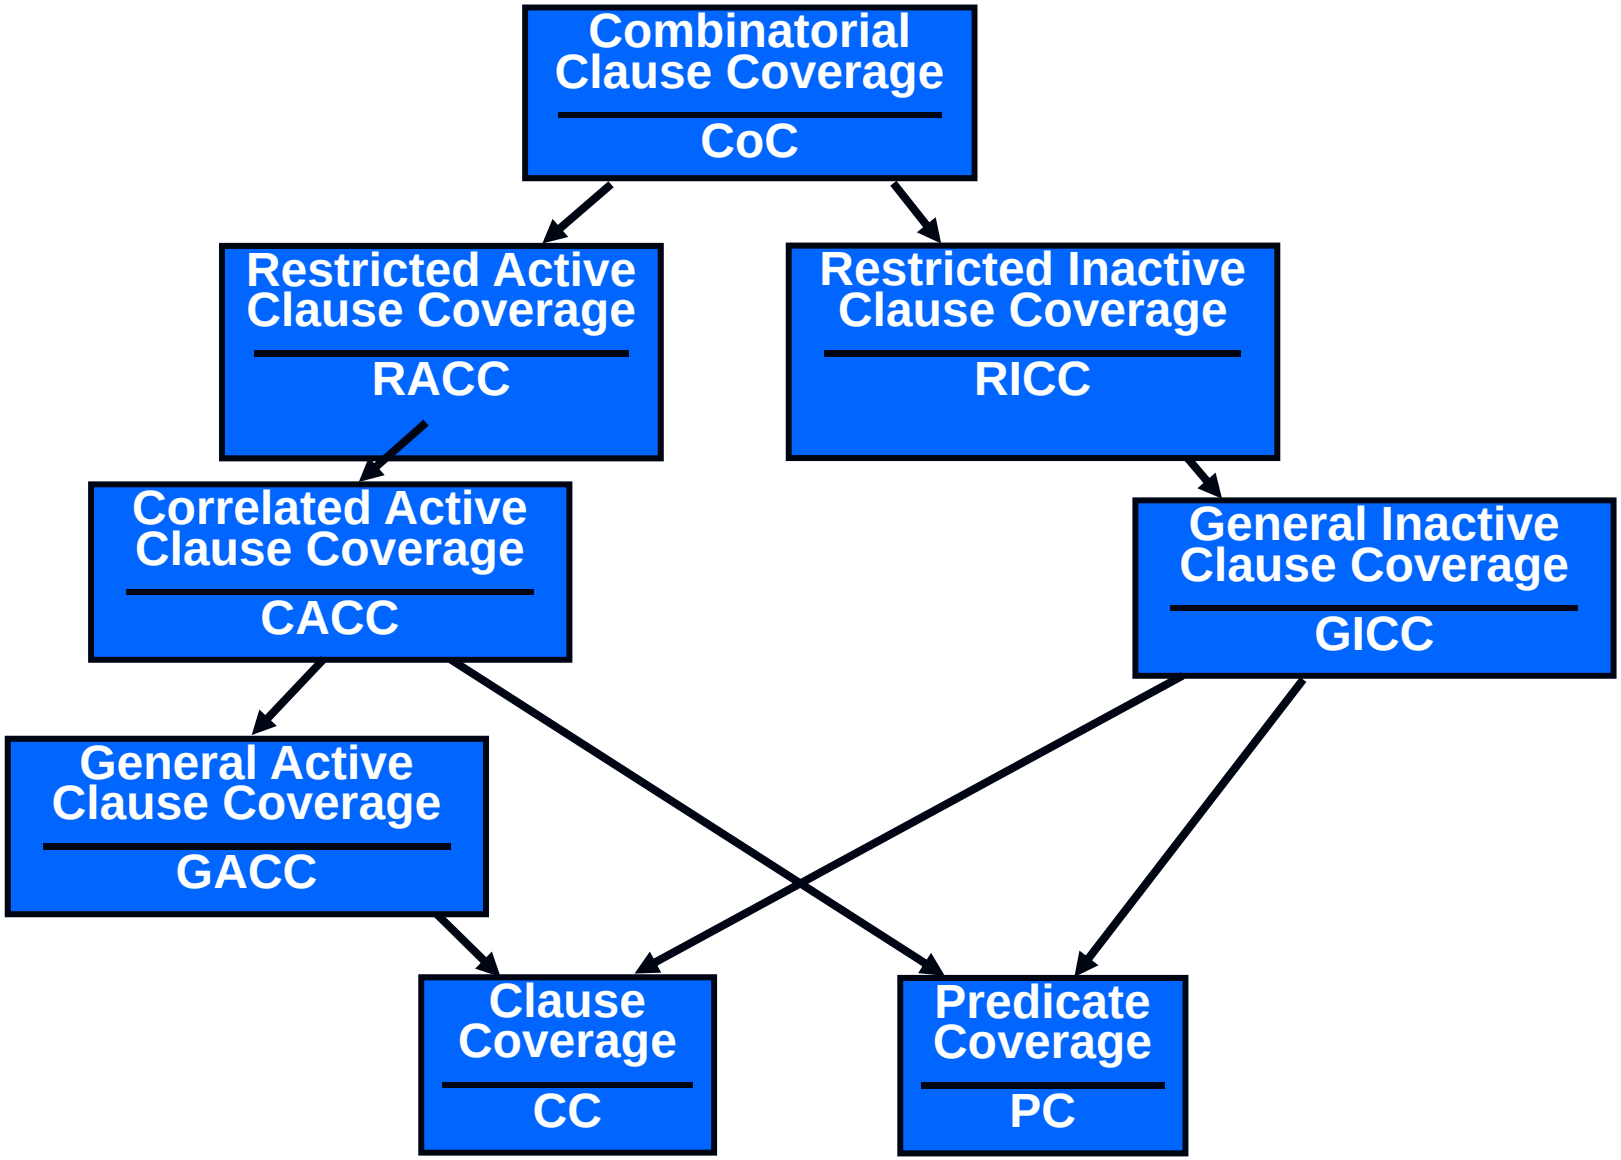
- Unlike ACC, the notion of correlation is not relevant
  - c_i does not determine p, so cannot correlate with p
- Predicate coverage is always guaranteed

General Inactive Clause Coverage (GICC) : For each *p* in *P* and each major clause c_i in *Cp*, choose minor clauses c_j, *j != i*, so that c_i does not determine *p*. The values chosen for the minor clauses c_j do not need to be the same when c_i is true as when c_i is false, that is, $c_j(c_i = true) = c_j(c_i = false)$ for all c_j OR $c_j(c_i = true)$!= $c_j(c_i = false)$ for all c_j.

Restricted Inactive Clause Coverage (RICC) : For each *p* in *P* and each major clause c_i in *Cp*, choose minor clauses c_j, *j != i*, so that c_i does not determine *p*. The values chosen for the minor clauses c_j must be the same when c_i is true as when c_i is false, that is, it is required that $c_j(c_i = true) = c_j(c_i = false)$ for all c_j.

KAIST

Logic Coverage Criteria Subsumption



KAIST

Making Clauses Determine a Predicate

- Finding values for minor clauses c_j is easy for simple predicates
- But how to find values for more complicated predicates ?
- Definitional approach:
  - $p_{c=true}$ is predicate p with every occurrence of c replaced by *true*
  - $p_{c=false}$ is predicate p with every occurrence of c replaced by *false*
- To find values for the minor clauses, connect $p_{c=true}$ and $p_{c=false}$ with exclusive *OR*

$$p_c = p_{c=true} \oplus p_{c=false}$$

- After solving, p_c describes exactly the values needed for c to deter mine p

Examples

$p = a \vee b$

$p_a = p_{a=true} \oplus p_{a=false}$
$= (true \vee b)$ XOR $(false \vee b)$
$=$ true XOR b
$= \neg b$

$p = a \wedge b$

$p_a = p_{a=true} \oplus p_{a=false}$
$= (true \wedge b) \oplus (false \wedge b)$
$= b \oplus$ false
$= b$

$p = a \vee (b \wedge c)$

$p_a = p_{a=true} \oplus p_{a=false}$
$= (true \vee (b \wedge c)) \oplus (false \vee (b \wedge c))$
$=$ true $\oplus (b \wedge c)$
$= \neg (b \wedge c)$
$= \neg b \vee \neg c$

- "*NOT b* $\vee$ *NOT c*" means either *b* or *c* can be false
- RACC requires the same choice for both values of *a*, CACC does not

KAIST

A More Subtle Example

$p = (a \wedge b) \vee (a \wedge \neg b)$

$p_a = p_{a=true} \oplus p_{a=false}$

$= ((true \wedge b) \vee (true \wedge \neg b)) \oplus ((false \wedge b) \vee (false \wedge \neg b))$

$= (b \vee \neg b) \oplus false$

$= true \oplus false$

$= true$

$p = (a \wedge b) \vee (a \wedge \neg b)$

$p_b = p_{b=true} \oplus p_{b=false}$

$= ((a \wedge true) \vee (a \wedge \neg true)) \oplus ((a \wedge false) \vee (a \wedge \neg false))$

$= (a \vee false) \oplus (false \vee a)$

$= a \oplus a$

$= false$

- ***a*** **always determines the value of this predicate**
- ***b*** **never determines the value – *b* is irrelevant !**

KAIST

Infeasible Test Requirements

- Consider the predicate:

$$(a > b \wedge b > c) \vee c > a$$

- $(a > b) = true, (b > c) = true, (c > a) = true$ is infeasible

- As with graph-based criteria, infeasible test requirements have to be recognized and ignored

- Recognizing infeasible test requirements is hard, and in general, undecidable

Example

$p = a \wedge (\neg b \vee c)$

	a	b	c	p	p_a	p_b	p_c
1	T	T	T	T	T	F	T
2	T	T	F	F	F	T	T
3	T	F	T	T	T	F	F
4	T	F	F	T	T	T	F
5	F	T	T	F	T	F	F
6	F	T	F	F	F	F	F
7	F	F	T	F	T	F	F
8	F	F	F	F	T	F	F

- Conditions under which each of the clauses determines p
  - p_a: $(\neg b \vee c)$
  - p_b: $a \wedge \neg c$
  - p_c: $a \wedge b$

- All pairs of rows satisfying GACC
  - a: {1,3,4} x {5,7,8}, b: {(2,4)}, c:{(1,2)}
- All pairs of rows satisfying CACC
  - Same as GACC
- All pairs of rows satisfying RACC
  - a: {(1,5),(3,7),(4,8)}
  - Same as CACC pairs for b, c
- GICC
  - a: {(2,6)} for p=F, no feasible pair for p=T
  - b: {5,6}x{7,8} for p=F, {(1,3) for p=T
  - c: {5,7}x{6,8} for p=F, {(3,4)} for p=T
- RICC
  - a: same as GICC
  - b: {(5,7),(6,8)} for p=F, {(1,3)} for p=T
  - c: {(5,6),(7,8)} for p=F, {(3,4)} for p=T

KAIST

Logic Coverage Summary

- Predicates are often very simple—in practice, most have less t han 3 clauses
  - In fact, most predicates only have one clause !
  - With only clause, PC is enough
  - With 2 or 3 clauses, CoC is practical
  - Advantages of ACC and ICC criteria significant for large predicates
    - CoC is impractical for predicates with many clauses

- Control software often has many complicated predicates, with lots of clauses
  - Question … why don't complexity metrics count the number of clauses in predicates?
